

Heterogeneity downgrade did not predict replication
Difference not significant (Fisher $P = 0.27$); denominators differ:
jointly estimable 167/173 robust vs 98/119 intermediate genes

Identifier matching: +34 genes, 34/34 replicated
FDR family: ± 2 genes

Moderate heterogeneity did not mark genes that failed replication; gene-identifier handling, not the FDR family, changed how many locked genes could be tested and replicated
